Abstract

The synthesis of a series of benzimidazole-\textit{N}-benzylpropan-1-amines and adenine-\textit{N}-benzylpropan-1-amines is described. Subsequent evaluation against two strains of the anaerobic bacterium \textit{Clostridium difficile} was performed with three amine derivatives displaying MIC values of 16 \(\mu\text{g/mL}\). Molecular docking studies of the described amines determined that the amines interact within two active site pockets of \textit{Clostridium difficile} methionyl tRNA synthetase with methoxy substituents in the benzyl ring and an adenine biaryl moiety resulting in optimal binding interactions.

Keywords

Methionyl-tRNA synthetase, \textit{Clostridium difficile}, 3-biaryl-\textit{N}-benzylpropan-1-amines, molecular modeling, MetRS-ligand interactions
Introduction

The *Clostridium difficile* infection (CDI) rate has shown a dramatic increase over the past decade and this increase is associated with the emergence of hypervirulent strain B1/NAP1/027\(^1\). CDI can also now be found more commonly outside healthcare facilities and in previously low-risk groups, such as children, pregnant women, and individuals with irritable bowel syndrome\(^2\). Recently CDI has exceeded MRSA as the most common healthcare facility-associated infection\(^3\). First-line treatment for CDI is usually metronidazole or vancomycin, for patients with severe infection, oral vancomycin is the preferred therapy as the clinical cure rate for vancomycin in patients with severe CDI was significantly better than that for metronidazole\(^4\). Unfortunately, recurrent disease occurs in 20 to 25% of patients receiving metronidazole and vancomycin\(^5\). For this reason there is a need to exploit other *C. difficile* targets in the development of new therapies. A promising target is aminoacyl-tRNA synthetase (aaRS).

Research in our lab in Cardiff has focused on methionyl tRNA (MetRS) as an antibacterial target, using our published homology model of *Clostridium difficile* MetRS\(^6\) to aid the design process. Most MetRS inhibitors studied are against *Staphylococcus aureus* and *Escherichia coli*. These inhibitors are divided into either adenosine or non-adenosine analogues. Adenosine analogues (Figure 1) are thought to mimic the high-energy intermediate aminoacyl-AMP, thus blocking the aaRS pocket\(^7\). Non-adenosine analogues may have vast structural differences compared with the natural substrate aminoacyl-AMP, but they still have good enzyme inhibitory activity. The challenge for MetRS inhibitors however is not biochemical activity but whole-cell activity. The most potent examples at the biochemical level, with IC\(_{50}\) values in the low nanomolar range, including oxazolone dipeptides and methionyl adenylate...
isosteres, have shown good selectivity versus human MetRS but lack antibacterial activity in whole-cell assays.

Figure 1 here

To date, REP3123 (Figure 1), a novel diaryldiamine, is the only documented selective \textit{C. difficile} MetRS inhibitor with whole cell activity in a range of clinical \textit{C. difficile} isolates. REP3123 is reported to have good \textit{in vitro} activity and selectivity against \textit{C. difficile}, while sparing other gut flora.

We report the efficient synthesis (Scheme 1) and whole cell activity against \textit{C. difficile} (Table 1) of a series of novel inhibitors incorporating pharmacophore elements of both REP3123 and adenosine analogues, namely: benzyl and biaryl moiety (adenine or benzimidazole) and flexible amine linker chain.

**Results and Discussion**

**Chemistry**

Treatment of benzimidazole (1) or adenine (2) with potassium carbonate followed by the addition of tert-butyl(3-bromopropyl)carbamate resulted in N-alkylation products 3 and 4 in yields of 76 and 68% respectively. Subsequent deprotection of BOC under acidic conditions gave the trifluoroacetic acid salts 5 and 6 in quantitative and 93% yield respectively. Imine formation was achieved on base catalyzed reaction of 5 and 6 with a range of benzaldehydes, giving the imine derivatives 7 and 8 in variable yields. NaBH\textsubscript{4} reduction of the imines gave the required benzimidazole and adenine \textit{N}-benzylpropan-1-amines 9 and 10 in good yields.

Scheme 1 here

**Microbiology**
A stock solution of each amine was prepared in 5% DMSO at a concentration of 256 μg/mL. These were then diluted with nutrient broth to final concentrations of 128 μg/mL, 64 μg/mL, 32 μg/mL, 16 μg/mL, 8 μg/mL, 4 μg/mL, 2 μg/mL, 1 μg/mL or 0.5 μg/mL and inoculated with a bacterial suspension of either *C. difficile* strain 1813 or strain R20291. Growth was assessed after incubation at 37 °C for 48 h in an anaerobic cabinet. Metronidazole as a control showed an MIC of <0.5 μg/mL for both *C. difficile* strain 1813 and R20291.

*Table 1 here*

Three amines 9e, 10a and 10e displayed MIC values of 16 μg/mL against *C. difficile* strain 1813 (Table 1) and one of the imines 8d showed activity with an MIC value of 16 μg/mL. None of the imines or amines showed inhibitory activity against strain R20291.

*Molecular modeling*

Docking interactions of the imines and amines were explored using molecular modeling software. REP3123 had previously been shown to fit in two pockets within the *C. difficile* MetRS active site. Pocket 1 (the methionine binding pocket) has Ile12, Asp51, Ala230 and Trp227 as the main residues, while Glu55, Ser133 and Tyr225 form an adjacent pocket (pocket 2) with Lys56 bridging the two pockets.⁶,¹¹

*Figure 2 here*

All the amines and imines had reasonable docking results based on both visual inspection of the poses and the docking score and occupied the two pockets previously observed for REP3123 (Figure 2). The adenine derivatives were found to give better interactions in terms of hydrogen bonding via the NH₂ and the 4-methoxy
and 3,5-dimethoxy derivatives were able to better fill the two pockets with additional hydrogen bonding interactions between a methoxy group and Lys59 (Figure 3). Ile12 was found to be the main key interaction in the methionine pocket, while Glu55, Lys59, Ala230 were found to be the main interactions in the adjacent pocket with Lys56 and Glu262 bridging these two pockets.

**Conclusions**

This study provides some insight into the functionality required for improved binding interactions within the two pockets of the MetRS active site, although there is still scope for further extension within the pockets. The whole cell activity observed for the imine 8d and amines 9e, 10a and 10e is promising for further development, however the different inhibitory activity observed with the two *C. difficile* strains highlights the challenges of developing a MetRS inhibitor that can inhibit a range of *C. difficile* clinical isolates.
